³Rabbit Production, Animal Production, Research Institute, Dokki – Giza

The present study was carried out on a flock of Bouscat rabbits belongs to El-Gemaiza Experimental Station, Animal Production Research Institute, Agriculture Research Center, Ministry of Agriculture, Egypt.

The experiment study lasted two months (from 6 up to 8 months of age) to investigate the effects of doses of garlic treatment on hematological, biochemical, hormonal and fertility parameters of male Bouscat rabbits. For this purpose, twenty four male Bouscat rabbits weighted 3150-3300 g were distributed into four experimental groups with equal number (n = 6). The first group was used as a control and subcutaneously injected with saline solution (1 ml of 0.9% NaCl), the second, third and fourth groups were subcutaneously injected once a week for 8 weeks with garlic 3, 9 and 27 mg/kg body weight, respectively.

Results showed that, the total numbers of RBCs and WBCs counts as well as Hb concentration in male rabbits treated with different doses of garlic (3, 9 or 27 mg/kg body weight, once a week for 8 weeks) were significantly (P ≤ 0.05 or P ≤ 0.01) increased by increasing the dose of garlic. Lower dose of garlic (3 mg/kg body weight) showed slight increases (P ≤ 0.05) in total protein and albumin levels and a slight decrease (P ≤ 0.05) in globulin level, the higher doses (9 and 27 mg/kg body weight) showed marked decreases (P ≤ 0.05) in total protein, albumin and globulin levels. The total lipid, total cholesterol and triglyceride levels in male rabbits treated with different doses of garlic were decreased by increasing the dose of garlic, this decrease was statistically significant (P ≤ 0.05 or P ≤ 0.01) with the higher doses (9 and 27 mg/kg body weight). Garlic treatment to buck rabbits elicited a slight increase in high-density lipoprotein (HDL) level, while it showed marked decreases in low-density lipoprotein (LDL) and very low-density lipoprotein (VLDL).
lipoprotein (VLDL) levels. The activity of AST enzyme for buck rabbits treated with different doses of garlic was insignificantly changed by increasing the dose of garlic. While, the lower dose of garlic (3 mg/kg body weight) slightly decreased \( (P \leq 0.05) \), ALT and ALP enzyme activities, the higher doses (9 and 27 mg/kg body weight) showed increases \( (P \leq 0.05) \) in ALT and ALP enzyme activities of male rabbits. Treatment of buck rabbits with different doses of garlic slightly insignificantly decreased the urea level and slightly insignificantly increased creatinine level. Testosterone levels in rabbits treated with different doses of garlic were increased by increasing the dose of garlic, however, this increase was statistically significant \( (P \leq 0.05) \) with the doses 9 and 27 mg/kg. Lower dose of garlic (3 mg/kg body weight) elicited increases in the ejaculate volume, concentration, the total output, the wave motions, the motility percentages, the percentages of live spermatozoa and the percentages of abnormal spermatozoa. However, the higher doses (9 and 27 mg/kg body weight) showed decreases in the ejaculate volumes, the wave motions and the motility percentages, but increased concentrations and abnormal spermatozoa.

**Conclusively,** it can be concluded that the lower doses of garlic can be safely used and improved fertility parameters of buck rabbits however, the higher doses may cause problems.

**Key words:** Garlic, blood hematological and biochemical, hormones, semen quality and buck rabbits

The potency of garlic has been acknowledged for over 5000 years. Garlic (*Allium sativum*), a member of the family Liliaceae, is a common food spice widely distributed and used all over the world as a condiment in various prepared food. Although there are many garlic supplements commercially available, they fall into one of four categories: fresh garlic, garlic oil, garlic powder and aged garlic extract (Tattelman, 2005).

Garlic contains more than 200 chemicals. It contains sulfur compounds (allicin, alliin and agoene), volatile oils, enzymes (allinase, peroxidase and miracynase), carbohydrates (sucrose and glucose), and minerals (selenium). It also contains amino acids (cysteine, glutamine, isoleucine and methionine), which help to protect cells from the harms of free radicals, bioflavonoids (quercetin and cyanidin, allistatin I and allistatin II and vitamins C, E and A), which help to protect us from oxidation agents and free radicals (Ayaz and Alposy, 2007).
Garlic and its constituents have been widely recognized as agents for prevention and treatment of cardiovascular diseases (Eilat-Adar et al., 2013), as well as for inhibition of tumors development, reduction of tumor mass and decrease the number of mitotic cells within tumors (Wallace et al., 2013). Previous studies have shown that garlic preparations possess many biological activities including antiparasitic (Salama et al., 2014), antifungal (Suleiman and Abdallah, 2014), antibacterial (Shaheen et al., 2015) and antioxidative (Asdaq, 2015) activities.

Garlic supplementation increased spermatogenesis and the quality of semen parameters in male rabbits (El-Amary and Abou-Warda, 2007). However, Hosseini and Khaki (2014) reported that garlic consumption decreased the quality of semen parameters in male rats. Concerning the male reproductive hormone (testosterone), dietary garlic increased testosterone level in male rats fed a high fatty diet (Omntoso et al., 2012). Other studies reported that garlic supplementation decreased testosterone level in male rats (Ebomoyi and Ahumibe, 2010).

The present study was designed to evaluate the effect of garlic treatment (3, 9 and 27 mg/kg body weight injected subcutaneously once a week for 8 weeks) on physiological and reproductive parameters of buck Bouscat rabbits.

**MATERIALS AND METHODS**

The present study was carried out on a flock of Bouscat rabbits belongs to El-Gemaiza Experimental Station, Animal Production Research Institute, Agriculture Research Center, Ministry of Agriculture, Egypt.

The experiment study lasted two months (from 6 up to 8 months of age) to investigate the effects of garlic treatment on hematological, biochemical, hormonal and fertility parameters of male Bouscat rabbits. For this purpose, twenty four male Bouscat rabbits weighted 3150-3300 g were distributed into four experimental groups with equal number (n = 6). The first group was used as a control and subcutaneously injected with saline solution (1 ml of 0.9% NaCl), the second, third and fourth groups were subcutaneously injected with garlic 3, 9 and 27 mg/kg body weight, respectively. Garlic powder preparation, Tomex (ATOS Pharma, Cairo, Egypt) was dissolved in physiological saline, and doses of 3, 9 and 27 mg/kg body weight were subcutaneously injected in the neck region of rabbits once a week for 8 weeks.

The bucks were housed separately in individual flat deck batteries (50 x 60 x 40 cm) with universal specification, provided with galvanized feeders
and automatic drinkers. All batteries were located in a naturally ventilated room. Buck rabbits were fed ad libitum a commercial pelleted ration containing 16.95% crude protein, 12.01 crude fibre and 2.77 fat and 7.95 ash. Clean fresh tape water was available at all the times ad libitum throughout the experimental period. All bucks were kept under the same managerial, hygienic and environmental conditions.

Blood samples (5 ml/each rabbit) were collected from the ear vein of male rabbits. Each sample was divided into two tubes; the first was heparinized and the second was non-heparinized. The heparinized blood samples were used to test hematological parameters. Non-heparinized blood samples were immediately centrifuged at 3000 r.p.m. for 15 minutes and serum was separated, frozen under -20°C, and kept for biochemical and hormonal assessment. Red blood cells (RBCs), white blood cells (WBCs) counts and hemoglobin (Hb) concentration were determined as described by Emad El-Eslam (1997).

Serum levels of total protein and albumen were determined according to Henry (1964) and Doumas et al. (1971), respectively, using commercial kits (Diamond diagnostics). The globulin value was obtained by subtracting the value of albumen from the corresponding value of total protein. Total lipid, high-density lipoprotein, low-density lipoprotein and very low-density lipoprotein levels were determined according to Zöllner and Kirsch (1962), while total cholesterol and triglyceride levels were determined according to Richmond (1973) and Fassati and Prencipe (1982), respectively, using commercial kits (Diamond diagnostics). The activity of aspartate amino-transferase (AST) and alanine amino-transferase (ALT) were assayed according to Reitman and Frankel (1957) and the activity of alkaline phosphate (ALP) was assayed according to Belfield and Goldberg (1971). Urea-N and creatinine levels were determined using commercial kits (Diamond diagnostics) according to the method of Patton and Crouch (1977) and Henry (1974), respectively.

Serum level of testosterone was measured using Coat-A-Count Total Testosterone (PITKTT-5, 2006-12-29) radioimmunoassay kits according to the method of Demetriou (1987). Serum level of tri-iodothyronine (T₃) was measured using Coat-A-Count Total T₃ (PITKT3-7, 2009-07-16) radioimmunoassay kits according to the method of Hollander and Shenkman (1974). Serum level of thyroxine (T₄) was measured using Coat-A-Count Total T₄ (PITKT4-4, 2006-03-18) radioimmunoassay kits according to the method of Albertini and Ekins (1982).

After four weeks of injection, semen samples were collected twice a week for four weeks using an artificial vagina device. Ejaculate volume,
EFFECT OF DOESES OF GARLIC ON RABBITS

sperm concentration, total output, wave motion, sperm motility %, live spermatozoa % and abnormal spermatozoa % were estimated according to the procedures of El-Kelawy (1993).

Least Square Maximum Likelihood method of analysis (SPSS, 2004) was used to analyze the obtained data according to the following model:

\[ Y_{ij} = \mu + T_i + e_{ij}, \]

Where: \( Y_{ij} \) is any observation, \( \mu \) is the overall mean of observation, \( T_i \) is the effect of treatment and \( e_{ij} \) is the random error.

Duncan’s New Multiple Range test was used for multiple comparisons (Duncan, 1955).

RESULTS AND DISCUSSION

Effect of garlic treatment on blood indices:

Data in Table 1 showed that the total numbers of RBCs and WBCs counts as well as Hb concentration in male rabbits treated with different doses of garlic (3, 9 or 27 mg/kg body weight, once a week for 8 weeks) were significantly (\( P \leq 0.05 \) or \( P \leq 0.01 \)) increased by increasing the dose of garlic. The percentages of this increase reached 8.1, 24.6 and 38.9% for RBCs , 30.7, 37.7 and 79.4% for WBCs and7.2, 24.2 and 38.5% for Hb  as compared with that of the corresponding control value, respectively.

Garlic treatment increased the number of RBCs, WBCs counts and Hb concentration in male rabbits (Al-Jowari, 2014). Garlic significantly prevented the reduction of RBCs caused by lead intoxification (Ouarda and Abd-Ennour, 2011) in rabbits. However, Suleria et al. (2013b) reported that rabbits treated with garlic showed insignificant reduction in RBCs count. Fazlolahzadeh et al. (2011) suggested that garlic contains some constituents that may play a role in the function of organs related to blood cell formation such as thymus, spleen, and bone marrow to stimulate more blood production. In addition, Samson et al. (2012) suggested garlic compounds might have a stimulatory effect on some haematopoetic growth factors (cytokines) which interact with specific receptors on the surface of haematopoietic cells, regulating the proliferation and differentiation of progenitor cells and the maturation and functioning of mature cells. Chemical components of garlic seem to act as active oxygen scavenger competes with hemoglobin in the RBCs for oxygen resulting in tissue hypoxia, which in turn stimulates the kidney to form and secrete

The end-product of metabolism of garlic in the body may also step up Hb synthesis and RBC production by their indirect effect on erythropoietin (Fazlolahzadeh et al., 2011). Also, garlic contain natural sulfur compounds which act as antioxidant active substances that implies the antioxidant action of garlic sulfhydryl groups on RBCs counts (Attia and Ali, 1993). Moreover, William (1999) reported that several vitamins like vitamin B₁, B₂, B₆, B₉, C and E are present in garlic have a role in RBCs formation, maturation and in hemoglobin biosynthesis, absorption and utilization. Regarding effect of garlic on WBCs count, Onu and Aja (2011) reported garlic might help in boosting the immune system of the rabbits. Iranloye (2002) suggested the anti-infection properties of garlic that stimulate immune functions. Also, garlic possess some important phytochemicals such as flavonoids, steroidal glycosides, alkaloids, saponins, tannins, phenolics, pectin and amino acids, with their biological and physiological roles to stimulate the immune system and organs related to blood cell formation particularly the bone marrow (Jeorg and Lee, 1998).

**Effect of garlic treatment on serum protein fractions:**

The present study showed that the lower dose of garlic (3 mg/kg body weight) showed slight increases (P ≤ 0.05) in total protein and albumin levels and a slight decrease (P ≤ 0.05) in globulin level, the higher doses (9 and 27 mg/kg body weight) showed marked decreases (P ≤ 0.05) in total protein, albumin and globulin levels (Table 2). The percentages of this change reached 10.8, -22.5 and -25.6% for total protein, 26.3, -13.2 and -7.9% for albumin and -8.5, -34.2 and -47.6% for globulin as compared with that of the corresponding control value, respectively. The A/G ratios in male

rabbits treated with different doses of garlic were insignificantly increased by increasing the dose of garlic.

Albumins and globulins are two key components of serum proteins. As albumin synthesizes in the liver, it can be used as a biomarker to monitor liver function (Friedman \textit{et al.}, 1980). Hussein \textit{et al.} (2007) suggested that garlic has ability to stimulate the regeneration of hepatic tissue, which increases protein synthesis in damage liver, improves the functional status of the liver cells and prevent protein oxidation. In addition, it is believed that garlic affect whole body protein metabolism through hormonal regulation by stimulating adrenaline and nor-adrenaline hormonal secretion (Srivastava and Pathak, 2012b). On the other hand, the decrease in protein levels, observed with higher doses in the present investigation may be due to their degradation and possible utilization for metabolic purposes and may attributed to the destruction or necrosis of cells and their consequent impairment in protein synthesis machinery (Srivastava and Pathak, 2012b).

Effect of garlic treatment on total lipid, total cholesterol and triglyceride levels:

The present data in Table 3 showed that the total lipid, total cholesterol and triglyceride levels in male rabbits treated with different doses of garlic were decreased by increasing the dose of garlic, this decrease was statistically significant \((P \leq 0.05\) or \(P \leq 0.01\)) with the higher doses (9 and 27 mg/kg body weight). The percentages of this decrease reached -23.4, -51.0 and -58.4\% for the total lipid, -3.6, -21.7 and -40.4\% for cholesterol total cholesterol and 9.5, -29.8 and -37.1\% for triglyceride as compared with that of the corresponding control value, respectively.

Significance: ** = P ≤ 0.01

Addition of garlic extract to oxidized vegetable oil caused a significant reduction in total cholesterol and triglyceride levels in rabbits (Fiolka et al., 2004). Garlic supplementation also elicited a decrease in total cholesterol and triglyceride levels in rabbits (Suleria et al., 2013a). In addition, garlic administration reduced serum total cholesterol and triglyceride levels in hypercholesterolemic rabbits (Fyiad and El-Sayed, 2012). Moreover, garlic administration decreased the levels of total cholesterol and triglyceride in diabetic rabbits (Rind et al., 2013). These compounds may exert their anti-cholesterolemic effect by three different mechanisms: by inhibiting hepatic cholesterol biosynthesis (Singh and Porter, 2006); by enhancing cholesterol turnover to bile acids and its excretion through gastrointestinal tract (Srinivasan and Sambaiah, 1991); or by inhibiting cholesterol absorption from intestinal lumen (Slowing et al., 2001). Moreover, other non-sulphur components of garlic, such as steroid saponins, might also be able to reduce lipids and cholesterol biosynthesis (Omojola et al., 2009).

Effect of garlic treatment on high-density lipoprotein (HDL), low-density lipoprotein (LDL) and very low-density lipoprotein (VLDL) levels:

Results showed that garlic treatment to male rabbits elicited a slight increase in high-density lipoprotein (HDL) level, while it showed marked decreases in low-density lipoprotein (LDL) and very low-density lipoprotein (VLDL) levels (Table 4). The percentages of this increase reached 12.7, 2.0 and 8.7% for(HDL), -13.1, -31.4 and -66.4% for (LDL) and -9.3, -29.7 and -37.1% for(VLDL) as compared with that of the corresponding control value, respectively.

Results are consistent with the results of Fiolka et al. (2004) who reported adding garlic extract to oxidized rapeseed oil caused a significant

increase the level of HDL in rabbit. Treatment with different doses of aqueous garlic extracts also caused a reduction in LDL and VLDL levels and increased the level of HDL in rabbits (Suleria et al., 2013a). Different studies reported that garlic and its constituents decreased LDL and increased HDL levels in hyperlipidemic rabbits (Fyiad and El-Sayed, 2012). The protective effects of garlic may be attributed to inhibition of enzymes involved in lipid synthesis, prevention of lipid peroxidation and LDL, and increasing antioxidant activity (Rahman and Lowe, 2006). Dillon et al. (2003) reported that garlic inhibits the in vitro oxidation of isolated human LDL by scavenging superoxide and inhibiting the formation of lipid peroxides; and protects cellular structures against peroxidation, which act as inhibitors for some enzymes, such as hydroxyl methyl glutaryl CoA reductase (Ashraf et al., 2005). Moreover, garlic appears to inhibit hepatic fatty acid synthesis by lowering key enzymes activities in supplying substrates, and to prevent lipid implantation on the arterial wall (Abramovitz et al., 1999). The hypolipidaemic activities of garlic may be also attributed to other non-sulphur components, like the steroid saponins (Omojola et al., 2009).

Effect of garlic treatment on serum enzyme activities of the liver:

The activity of AST enzyme in male rabbits treated with different doses of garlic was insignificantly changed by increasing the dose of garlic (Table 5). While, the lower dose of garlic (3 mg/kg body weight) slightly decreased (P ≤ 0.05), ALT and ALP enzyme activities, the higher doses (9 and 27 mg/kg body weight) showed increases (P ≤ 0.05) in ALT and ALP
enzyme activities of male rabbits. The percentages of this change reached -5.9, 1.6 and 5.3% for AST, -12.0, 14.2 and 27.9% for ALT and -28.5, 10.9 and 40.4% for ALP in comparison with that of the control value, respectively.

Abd and Al-Baghdadi (2009) reported that administration of aqueous garlic extract restored AST and ALT enzymes activities induced by carbon tetrachloride in male rabbits. Aletan and Eteng (2013) also reported that oral administration of garlic extract increased AST enzyme activity by increasing the doses in rats. Ajayi and Ajayi (2014) reported that AST and ALP enzyme activities were decreased with lower dose of garlic powder, but increased with higher dose in hypercholesterolemic rats.

**Effect of garlic treatment on kidney function:**

Results in Table (6) showed that treatment of male rabbits with different doses of garlic slightly insignificantly decreased the urea level and slightly insignificantly increased creatinine level. The percentages of this increase reached -4.5, -10.9 and -0.4% for urea level and 4.9, 2.4 and 12.2% for creatinine level as compared with that of the corresponding control value, respectively. Administration of garlic extract decreased the levels of urea and creatinine in diabetic rabbits (Rind et al., 2013) or normal rabbits (Suleria et al., 2013b). On the other hand, Mahmoodi et al. (2006) found that administration of raw garlic did not change urea and creatinine levels in human. Omurtag et al. (2005) reported that garlic and its components provide protection against free radical damage in the body through their antioxidant activities. The antioxidative activities of garlic could also be

related to its contents of cysteine-containing bioactive compounds, selenocompounds and flavonoids (Banerjee and Maulik, 2002).

**Effect of garlic treatment on testosterone hormone level:**

Testosterone levels in rabbits treated with different doses of garlic were increased by increasing the dose of garlic (Table 7). However, this increase was statistically significant ($P \leq 0.05$) with the doses 9 and 27 mg/kg body weight. The percentages of this increase reached 12.5, 27.4 and 24.7% as compared with that of the corresponding control value, respectively. Testosterone hormone was significantly higher in garlic-fed male rabbit (El-Amary and Abou-Warda, 2007). El-Shafey et al. (2009) attributed the garlic-induced increase in testosterone level to the elevation of sex hormone binding globulin, which binds more testosterone, and consequently, oblige the testis to excrete more male sex hormone in plasma. Oi et al. (2001) suggested that garlic supplementation might enhance protein anabolism and suppress protein catabolism due to hormonal regulation by the stimulation of steroid hormones, leading to greater testis testosterone content and lower plasma corticosterone concentration. Mirfardi and Johari, (2015) suggested that garlic compounds are responsible for the significant increase in testosterone levels by affecting the performance of steroid-generating enzymes, testosterone hormone and its metabolites. They concluded that garlic supplementation likely increases testicular testosterone content due to the stimulation of LH secretion from the pituitary gland, which stimulate the testes to increase its testosterone production.

**Effect of garlic treatment on physical semen characteristics:**

The present study showed that the lower dose of garlic (3 mg/kg body weight) elicited increases in the ejaculate volume, concentration, the total output, the wave motions, the motility percentages, the percentages of live spermatozoa and the percentages of abnormal spermatozoa (Table 8).

a and b means with different super-script in the same column, differ significantly \((P \leq 0.05)\).

* = \(P \leq 0.05\) and NS = Not significant.

On the other hand, the higher doses (9 and 27 mg/kg body weight) showed decreases in the ejaculate volumes, the wave motions and the motility percentages, but increased concentrations and abnormal spermatozoa. These results are in good accordance with the results of El-Amary and Abou-Warda (2007) who found that quality of semen parameters was significantly higher after adding garlic to male rabbit diets. The present results are also consistent with the results of Ouarda and Abd-Ennour (2011) who found that treatment of rabbits with row garlic restored lead-induced decrease in sperm speed, motility and viability.

Conclusively, the present study confirms the health and medicinal benefits of garlic. The dose of garlic plays a key role in determining, which effect its administration would have on the physiology and biochemistry of
the body organs. While the lower doses of garlic can be safely used, the higher doses may cause problems. The lower dose of garlic improved fertility parameters of buck rabbits.

الملخص العربي
تأثر المعاملة بالثوم على التركيب الكيميائي للدم والهرمونات وقياسات الخصوبة في ذكور الأرانب البويسكات

حسن محمود الكيلاوي، مروفة أبو منصور، راندا عز الدين التجار، نبيلة السيد محمود
الحبيبي، مركز البحوث الزراعية، وزارة الزراعة، مصر

استمرت التجربة مدة شهرين (من 6 حتى 8 أشهر من العمر) لدراسة تأثير الجرعات العلاجية من الثوم على التركيب الكيميائي للدم والهرمونات والخصوبة في ذكور الأرانب بواسكنت. لهذا الغرض، تم استخدام 24 ذكر من أرانب بواسكنت. تم استخراج مجموعات من طاقة (ن = 6)، استخدمت المجموعات الأولى كgrupo محاكاة، وتحت الظلم بحلول ملحية (10% من كلوريدي مصبوغ، 0.9%)، أما المجموعات الثانية والثالثة والرابعة فقد خفت تحت الظلم المسترور بالحمض (3، 9، 27 ملجم / كجم من وزن الجسم). على التوالي أظهرت التجربة أن المعالجة بجرعات الثوم (3، 9، 27 ملجم / كجم من وزن الجسم) قد أدت إلى زيادة معنوية (على مستوى احتمال 5% أو 1%) في عدد كرات الدم الحمراء والبيضاء، وكذلك تركز الليمفوبلازم بسبب الجرعة المستخدمة.

أظهرت التجربة أن المعالجة بالجرعة الأقل من الثوم (3 ملجم / كجم من وزن الجسم) قد أدت إلى زيادة مستوى البروتين الكلي، والألبومين، ونقص مستوى الجلوبولين، بينما أظهرت الجرعات بالجرعتين الأعلى (9 و 27 ملجم / كجم من وزن الجسم) نقصاً ملحوظاً في مستوى البروتين الكلي والألبومين والجلوبولين. وقد انخفض مستوى البروتين الكلي للدهون والكولسترول، وكذلك الجليسينات الثلاثية زيادة الجرعة، وكان هذا الانخفاض واضحًا مع الجرعينين الأعلى (27 ملجم / كجم من وزن الجسم). بينما زاد مستوى البروتين الدهني عملي الكثافة زيادة غير معنوية، في حين انخفض مستوى كلي غير معنوي في شئان الكثافة وخصوصاً كثافة نبضية مرتفعة ورائدة الجرعة (AST, ALT, ALP) بالإراثيات عند الجرعة (3 ملجم / كجم من وزن الجسم) (الإضافة إلى ذلك، فقد انخفض مستوى البروتين الكرياتينين بنسبة ملحوظة زيادة الجرعة.

أظهرت التجربة أن المعالجة بالجرعة من ثوم جربعه المختلفة قد أدت إلى زيادة واضحة في مستوى هرمون الاستروسترون، وقد كانت هذه زيادة غير معنوية مع الجرعة (3 ملجم / كجم من وزن الجسم) ومعنوية مع الجرعين (9 و 27 ملجم / كجم من وزن الجسم).

أظهرت التجربة زيادة غير معنوية في كل من هرمون التستوسترون والجرعة (3 ملجم / كجم من وزن الجسم)، بينما كان هناك نقص غير معنوي في كل من هرمون الانتقادات المنوية والجرعتين الأعلى (9 و 27 ملجم / كجم من وزن الجسم). في الجرعين (3 ملجم / كجم من وزن الجسم) لم تظهر أي تأثير جذري على معايير الدم والخصائص الكيميائية والfts الهرمونية والهرمونات في ذكور الأرانب بواسكنت. ومع ذلك فإن الجرعات العلاجية قد تسبب مشاكل
